Engineering Statistics

Week 7: Confidence intervals

Reminder

An estimator of a population parameter is a random variable that depends on the sample information; its value provides approximations of this unknown parameter. A specific value of that random variable is called an estimate.

Parameter	Estimator (Statistic)	Estimate
μ	$ar{X}$	$ar{x}$

Confidence interval in material science

1. Material Strength Testing

Example: If the average elongation of a material under 1000 kg tensile force is 5 mm, but the test results show a confidence interval ranging from 4.5 mm to 5.5 mm, the confidence interval shows the uncertainty in the test measurement.

2. Microstructure Analysis

Example: If the average grain size of a material is found to be 10 micrometers, but the measurements show a confidence interval between 9.5 and 10.5 micrometers, this confidence interval represents the variation in the material's microstructure.

3. Performance Testing

Example: After a 1000-hour corrosion test, the corrosion rate of a material is found to be an average of 0.05 mm/year, but the test results show a confidence interval between 0.04 mm/year and 0.06 mm/year. This confidence interval provides insight into the variability of the corrosion rate.

4. Tolerances and Manufacturing Process Error

Example: During a manufacturing process, if the average length of a part is 50 mm, but the parts' lengths vary between 49.5 mm and 50.5 mm, the confidence interval can be used to understand the tolerance of the part dimensions.

Confidence interval estimation

Confidence interval estimator

A confidence interval estimator for a population parameter is a rule for determining (based on sample information) an interval that is likely to include the parameter. The corresponding estimate is called a **confidence interval** estimate.

Confidence interval and confidence level

- Let θ be an unknown parameter. Suppose that on the basis of sample information, random variables A and B are found such that $P(A < \theta < B) = 1 \alpha$ where α is any number between 0 and 1.
- If the specific sample values of A and B are a and b, then the interval from a to b is called a $100(1-\alpha)\%$ confidence interval of θ .
- The quantity $100(1-\alpha)\%$ is called the confidence level of the interval.

Confidence interval and confidence level

If the population is repeatedly sampled a very large number of times, the true value of the parameter θ will be covered by $100(1-\alpha)\%$ of intervals calculated in this way. The confidence interval calculated in this manner is written as,

$$a < \theta < b$$

with $100(1-\alpha)\%$ confidence.

Confidence interval for population mean μ

Assumptions

- (i) X_1, X_2, \ldots, X_n is a random sample drawn from a normal distribution with mean μ and variance σ^2 .
- (ii) Population mean μ is unknown but population variance σ^2 is known.

Reminder

Let random variables X_1, X_2, \ldots, X_n denote a random sample from a normal distribution with mean μ and variance σ^2 . Then, sampling distribution of the \bar{X} is normal with mean μ and variance $\frac{\sigma^2}{n}$, i.e.,

$$\bar{X} \sim N(\mu, \frac{\sigma^2}{n})$$
 or $Z = \frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \sim N(0, 1)$

 $100(1-\alpha)\%$ confidence interval of μ

$$\bar{x} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{x} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

where $z_{\alpha/2}$ is the value from the standard normal distribution such that the upper percentile (upper probability) is $\alpha/2$.

 $z_{\alpha/2}$ = upper $\alpha/2$ point of standard normal distribution

$$Z \sim N(0,1) \rightarrow P(Z > z_{\alpha/2}) = \alpha/2$$
 or $P(|Z| < z_{\alpha/2}) = 1 - \alpha$

Selected confidence levels and corresponding values of $z_{\alpha/2}$

$100(1-\alpha)\%$	$z_{\alpha/2}$		
90%	1.64		
95 %	1.96		
99 %	2.58		

The daily carbon monoxide (CO) emission from a large production plant will be measured on 25 randomly selected weekdays. The production process is always being modified and the current mean value of daily CO emissions μ is unknown. Data collected over several years confirm that, for each year, the distribution of CO emission is normal with a standard deviation of 0.8 ton. Suppose the sample mean is found to be $\bar{x}=2.7$ tons.

Construct a $95\,\%$ confidence interval for the current daily mean emission μ .

$$\bar{x} = 2.7 \text{ tons}$$

$$\sigma = 0.8$$
 tons

$$n = 25 \text{ days}$$

The 95% confidence interval for the current daily mean emission μ :

$$\bar{x} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{x} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$

$$2.7 - 1.96 \frac{0.8}{\sqrt{25}} < \mu < 2.7 + 1.96 \frac{0.8}{\sqrt{25}}$$

$$2.3864 < \mu < 3.0136$$

The tensile strength of a newly developed metal alloy will be measured on 20 randomly selected test specimens. The alloy's production process is constantly being refined, and the current mean value of the tensile strength is unknown. Data collected over several years indicate that, for each year, the tensile strength of the alloy follows a normal distribution with a standard deviation of 15 MPa. Suppose the sample mean tensile strength from the 20 specimens is found to be 320 MPa.

Construct a 99% confidence interval for the current daily mean tensile strength of the alloy.

```
\bar{x} =
```

 $\sigma =$

n =

The 99 % confidence interval for the ...

Note

If random samples of n observations are drawn repeatedly and independently from the population and $100(1-\alpha)\,\%$ confidence intervals are calculated, then over a very large number of repeated trials, $100(1-\alpha)\,\%$ of these intervals will contain the true value of the population mean.

How changes the length of confidence interval for the population mean,

- (i) if the population standard deviation (variance) gets larger for given $100(1-\alpha)\,\%$ and sample size n?
- (ii) if sample size n gets larger for given $100(1-\alpha)\%$ and population standard deviation (variance)?
- (iii) if $100(1-\alpha)\%$ gets larger for given sample size and population standard deviation (variance)?

How changes the length of confidence interval for the population mean,

- (i) if the population standard deviation (variance) gets larger for given $100(1-\alpha)\,\%$ and sample size n? The confidence interval gets larger
- (ii) if sample size n gets larger for given $100(1-\alpha)\%$ and population standard deviation (variance)? The confidence interval gets narrower
- (iii) if $100(1-\alpha)\%$ gets larger for given sample size and population standard deviation (variance)? The confidence interval gets larger

Assumptions

- (i) X_1, X_2, \ldots, X_n is a random sample drawn from a normal distribution with mean μ and variance σ^2 .
- (ii) Both population mean μ and population variance σ^2 are unknown.

We want to a $100(1-\alpha)\%$ confidence interval of the population mean μ .

Since population variance σ^2 is unknown, we cannot use the following fact here:

$$Z = \frac{\bar{X} - \mu}{\sigma / \sqrt{n}} \sim N(0, 1)$$

An intuitive approach is to replace σ by its estimator s in this formula.

If X_1, X_2, \ldots, X_n be sample drawn from $N(\mu, \sigma^2)$ where both μ and σ^2 are unknown. Then, the statistic defined as,

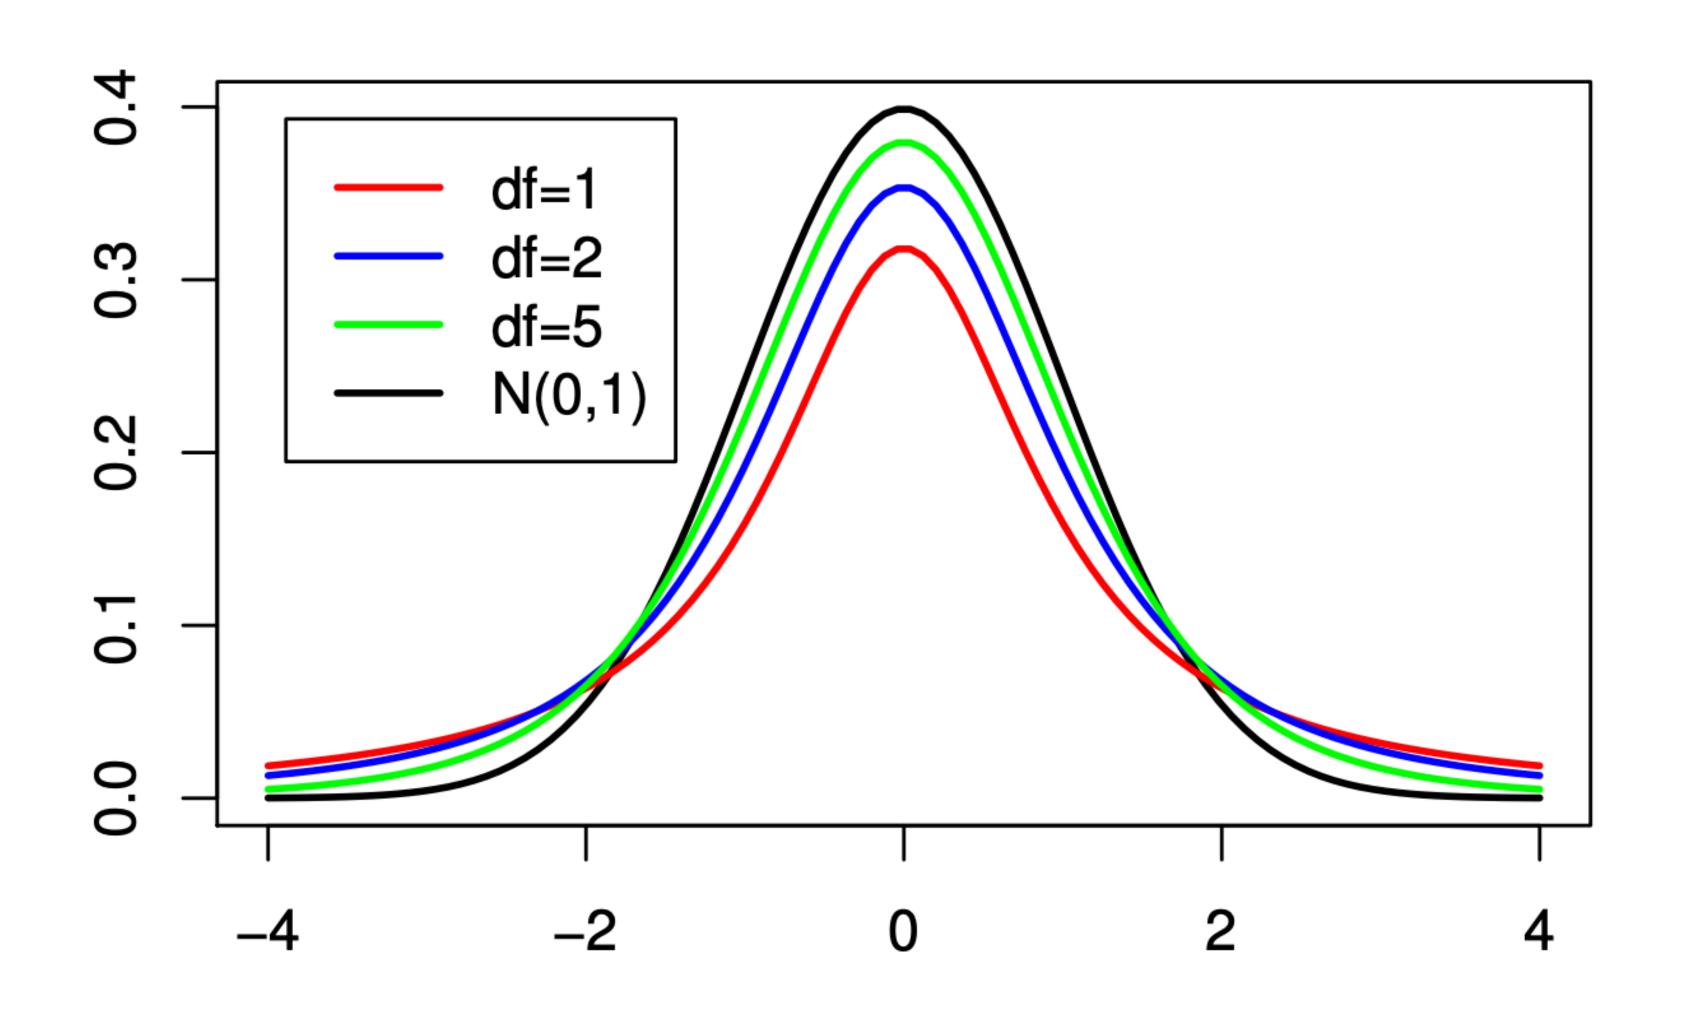

$$T = \frac{\bar{X} - \mu}{s / \sqrt{n}}$$

has Student's t distribution with degrees of freedom n-1.

Random variable T having Student's t distribution with degrees of freedom n-1 shortly denoted by,

$$T \sim t_{(n-1)}$$

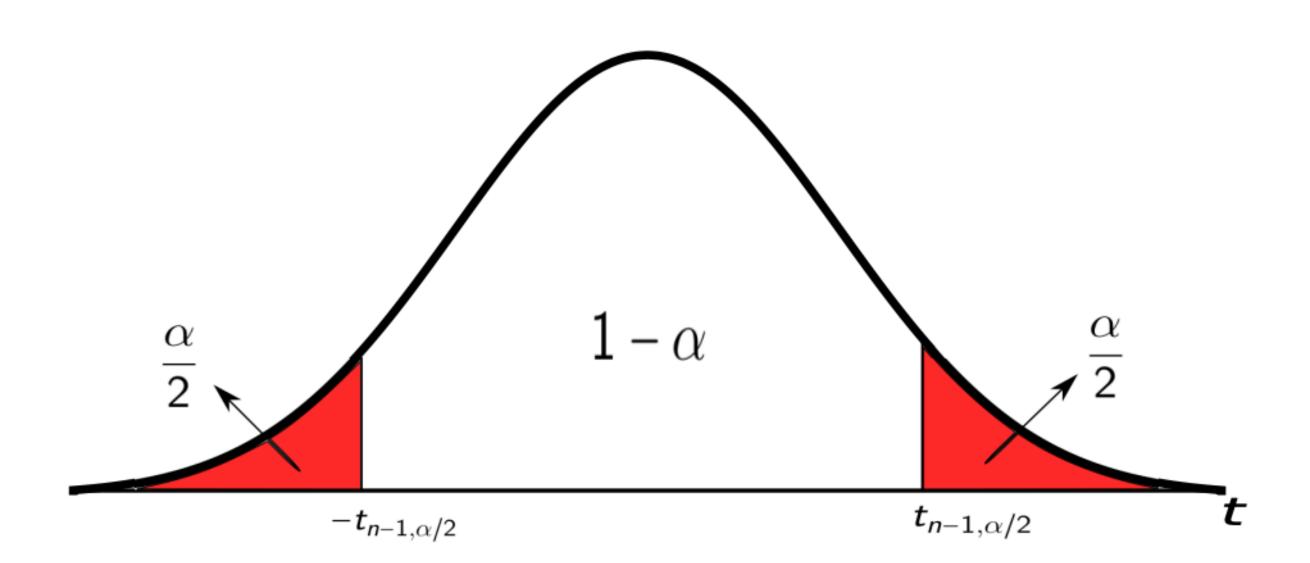

- A specific member of the family of Student's t distributions is characterized by the number of degrees of freedom associated with the computation of the standard error.
- The shape of the Student's t distribution is rather similar to that of the standard normal distribution. Both distributions have mean 0, and the probability density functions of both are symmetric about their means.
- However, the density function of the Student's t distribution has a wider dispersion (reflected in a larger variance) than the standard normal distribution.

Confidence interval

 $t_{n-1,\alpha/2}$ = upper $\alpha/2$ point of Student's t distribution

$$T \sim t_{(n-1)} \to P(T > t_{(n-1,\alpha/2)}) = \alpha/2$$
 or $P(|T| < t_{(n-1,\alpha/2)}) = 1 - \alpha$

Confidence interval

Suppose that X_1, X_2, \ldots, X_n be sample drawn from $N(\mu, \sigma^2)$ where both μ and σ^2 is unknown.

 $100(1-\alpha)\%$ confidence interval of μ :

$$\bar{x} - t_{(n-1,\alpha/2)} \frac{s}{\sqrt{n}} < \mu < \bar{x} + t_{(n-1,\alpha/2)} \frac{s}{\sqrt{n}}$$

where $t_{(n-1,\alpha/2)}$ is the value from Student's t distribution with degrees of freedom n-1 such that the upper percentile (upper probability) is $\alpha/2$.

Recently gasoline prices rose drastically. Suppose that a study was conducted using truck drivers with equivalent years of experience to test run 24 trucks of a particular model over the same highway. Estimate the population mean fuel consumption for this truck model with 90% confidence if the fuel consumption, in miles per gallon, for these 24 trucks was as follows:

15.5	21.0	16.5	19.2	18.6	19.1	18.5	19.3
19.7	16.9	18.7	18.2	18.0	17.5	19.8	18.0
19.8	18.2	20.2	14.5	18.5	20.5	20.3	21.8

$$n = 24$$
 trucks

$$\bar{x} = 18.68$$

$$s = 1.70$$

No information about the population variance -> means that "use t-distribution"

90% confidence interval for mean fuel consumption:

$$\bar{x} - t_{(n-1,\alpha/2)} \frac{s}{\sqrt{n}} < \mu < \bar{x} + t_{(n-1,\alpha/2)} \frac{s}{\sqrt{n}}$$

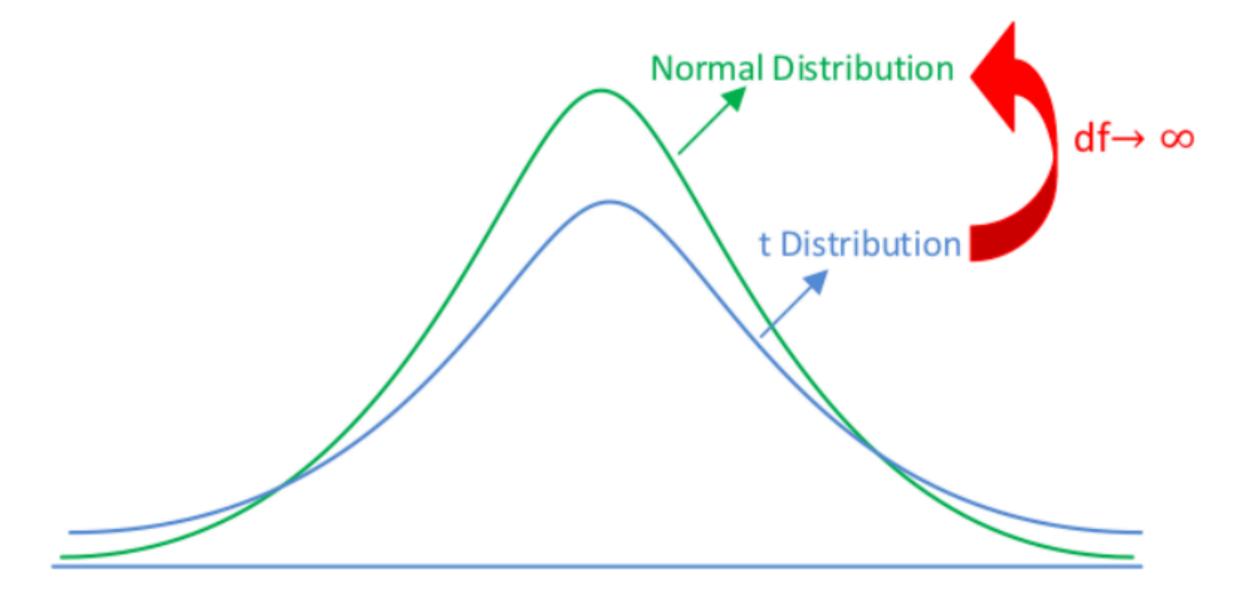

$$18.68 - t_{(23,10/2)} \frac{1.7}{\sqrt{24}} < \mu < 18.68 + t_{(23,10/2)} \frac{1.70}{\sqrt{24}}$$

$$18.68 - 2.069 \frac{1.7}{\sqrt{24}} < \mu < 18.68 + 2.069 \frac{1.70}{\sqrt{24}}$$

$$17.96 < \mu < 19.39$$

Note

- For larger values of the degrees of freedom, the Student's t distribution approaches to normal distribution.
- In other words, if n > 30 then Z table can be used instead of t table for computing the confidence interval of population mean μ .

Note

If n is large enough, the confidence interval for μ can be given as

$$\bar{x} - z_{\alpha/2} \frac{s}{\sqrt{n}} < \mu < \bar{x} + z_{\alpha/2} \frac{s}{\sqrt{n}}$$

even the population variance is unknown.

How much do students pay, on the average, for textbooks during the first semester of college? From a random sample of 400 students the mean cost was found to be \$375.75, and the standard deviation was \$37.89. Assuming that the population is normally distributed,

- (a) Find a 95% confidence interval for the population mean.
- (b) Find a 99% confidence interval for the population mean.
- (c) Compare the results obtained in (a) and (b).
- (d) Without doing the calculations, state whether an 80% confidence interval for the population mean would be wider than, narrower than, or the same as the answer to part (a).

$$n = 400$$

$$\bar{x} = 375.75 \text{ USD}$$

$$s = 37.89 \text{ USD}$$

No information about the population variance -> means that "use t-distribution", but we can use Z-distribution also because of n > 30

(a) The 95% confidence interval for the population mean:

$$\bar{x} - z_{\alpha/2} \frac{s}{\sqrt{n}} < \mu < \bar{x} + z_{\alpha/2} \frac{s}{\sqrt{n}}$$

$$375.75 - 1.96 \frac{37.89}{\sqrt{400}} < \mu < 375.75 + 1.96 \frac{37.89}{\sqrt{400}}$$

$$372.0367 < \mu < 379.4632$$

(b) The 99% confidence interval for the population mean:

$$\bar{x} - z_{\alpha/2} \frac{s}{\sqrt{n}} < \mu < \bar{x} + z_{\alpha/2} \frac{s}{\sqrt{n}}$$

$$375.75 - 2.58 \frac{37.89}{\sqrt{400}} < \mu < 375.75 + 2.58 \frac{37.89}{\sqrt{400}}$$

$$370.8621 < \mu < 380.6378$$

(c) The CI in (a) is narrower than the CI in (b) because of the confidence level.

The CI of population mean in (a) is (372.0367,379.4632)

The CI of population mean in (b) is (370.8621,380.6378)

(c) Without doing the calculations, state whether an 80% confidence interval for the population mean would be wider than, narrower than, or the same as the answer to part (a).

$$\bar{x} - z_{\alpha/2} \frac{s}{\sqrt{n}} < \mu < \bar{x} + z_{\alpha/2} \frac{s}{\sqrt{n}}$$

The Z value for 80% will be lower than the Z for 95% confidence level. This means that the CI for 80% confidence level will be narrower.

A company is evaluating the cost of producing a new type of **lithium battery** during its first production run. From a random sample of 400 batteries, the average production cost per battery was found to be **\$395.50**, and the standard deviation of the production cost was **\$42.10**. Assuming the population of production costs is normally distributed:

- (a) Find a 95% confidence interval for the population mean production cost.
- (b) Find a 99% confidence interval for the population mean production cost.

n =

 $\bar{x} =$

s =

(a) The 95% confidence interval for the population mean:

(b) The 99% confidence interval for the population mean:

Confidence interval for population variance σ^2

Intervals based on the normal distribution

Assumptions:

- (i) X_1, X_2, \ldots, X_n be a sample drawn from $N(0, \sigma^2)$ distribution.
- (ii) Population variance σ^2 is unknown.

We want a $100(1-\alpha)\%$ confidence interval of the population variance σ^2 .

If X_1, X_2, \ldots, X_n be a sample drawn from normal distribution having variance σ^2 . Then,

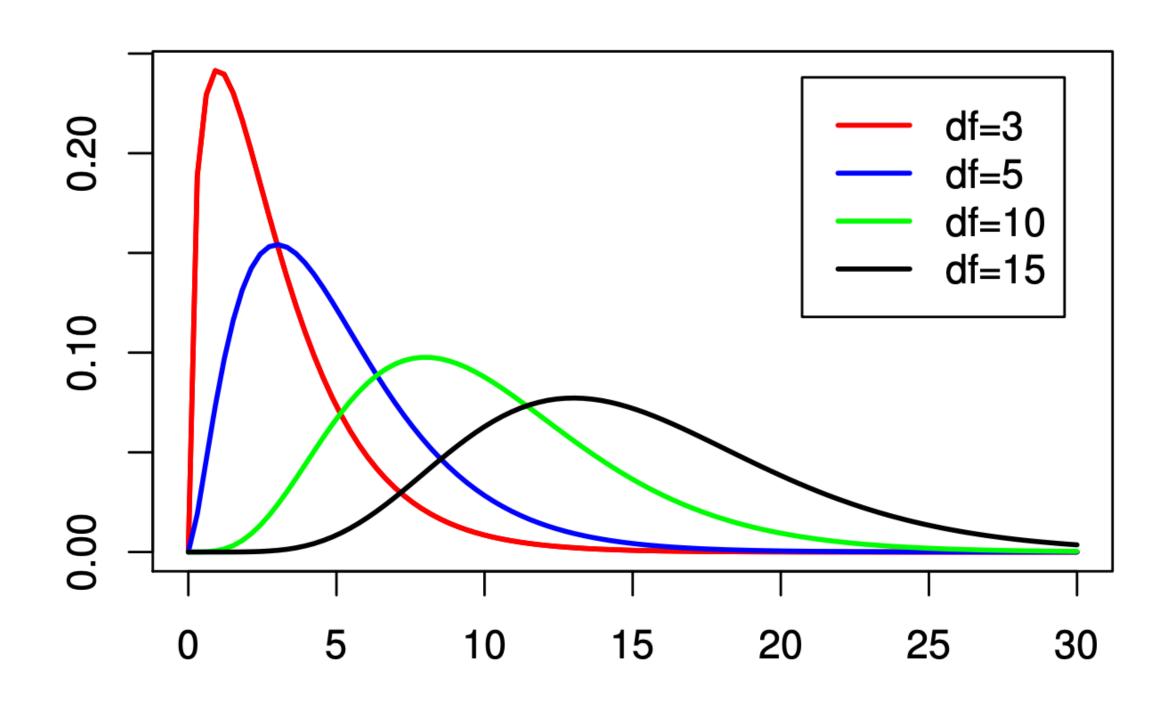

$$\chi^{2} = \frac{(n-1)s^{2}}{\sigma^{2}} = \frac{\sum_{i=1}^{n} (X_{i} - \bar{X})^{2}}{\sigma^{2}}$$

has chi-square distribution with degrees of freedom n-1.

Random variable χ^2 having chi-square distribution with degrees of freedom n-1 is shortly denoted by

$$\chi^2 \sim \chi_{n-1}^2$$

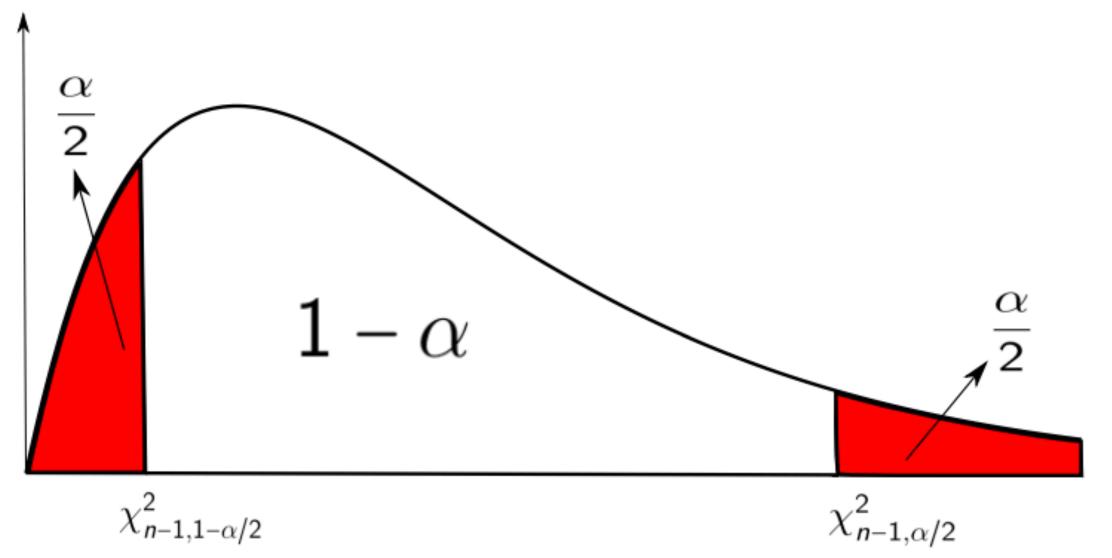

- The chi-square distribution, like the *t* distribution, is characterized by a quantity called the degrees of freedom associated with the distribution. In other words, the parameter of the chi-square distribution is its degree of freedom.
- Unlike normal and t distributions, the chi-square distribution is not symmetric around 0.

 $\chi_{n-1,\alpha/2}^2$ = upper $\alpha/2$ point of chi-square distribution.

 $\chi_{n-1,1-\alpha/2}^2$ = lower $\alpha/2$ point of chi-square distribution.

$$\chi^2 \sim \chi^2_{n-1} \to P(\chi^2 > \chi^2_{n-1,\alpha/2}) = \alpha/2$$
 and $\chi^2 \sim \chi^2_{n-1} \to P(\chi^2 > \chi^2_{n-1,1-\alpha/2}) = 1 - \alpha/2$

$100(1-\alpha)\%$ confidence interval of σ^2

Suppose that X_1, X_2, \ldots, X_n be sample drawn from a normal distribution having variance σ^2 which is unknown.

 $100(1-\alpha)\%$ confidence interval of σ^2 :

$$\frac{(n-1)s^2}{\chi_{n-1,1-\alpha/2}^2} < \sigma^2 < \frac{(n-1)s^2}{\chi_{n-1,\alpha/2}^2}$$

here $\chi^2_{n-1,1-\alpha/2}$ and $\chi^2_{n-1,\alpha/2}$ are the values from chi-square distribution with degrees of freedom n-1 such that the upper and lower percentiles are both $\alpha/2$.

The accompanying data on breakdown voltage of electrically stressed circuits was read from a normal probability plot that appeared in the article "Damage of Flexible Printed Wiring Boards Associated with Lightning-Included Voltage Surges" (IEEE Transactions on Components, Hybrids, and Manuf. Tech., 1985: 214-220). The straightness of the plot gave strong support to the assumption that breakdown voltage is approximately normally distributed.

1470, 1510, 1690, 1740, 1900, 2000, 2030, 2100, 2190, 2200, 2290, 2380, 2390, 2480, 2500, 2580, 2700

Compute the 95% confidence interval for the variance of the breakdown voltage distribution.

Compute the 95% confidence interval for the variance of the breakdown voltage distribution.

The CI of variance -> means use chi-square distribution

$$n = 17$$

 $s^2 = 137324.3$

$$\frac{(n-1)s^2}{\chi_{n-1,1-\alpha/2}^2} < \sigma^2 < \frac{(n-1)s^2}{\chi_{n-1,\alpha/2}^2}$$

$$\frac{(17-1)137324.3}{\chi_{16,0.975}^2} < \sigma^2 < \frac{(17-1)137324.3}{\chi_{16,0.025}^2}$$

$$\frac{(17-1)137324.3}{28.845} < \sigma^2 < \frac{(17-1)137324.3}{6.908}$$

$$76172.3 < \sigma^2 < 318064.4$$

Confidence interval for population proportion p

Sampling distribution of \hat{p}

• When n elements are randomly sampled from the population, the data will consists of the count X of the number of sampled elements possessing the characteristics. Common sense suggests the sample proportion

$$\hat{p} = \frac{X}{n}$$

as an estimator of p.

• When the sample size n is only a small fraction of the population size, the sample count X has the binomial distribution with mean np and variance np(1-p).

Sampling distribution of \hat{p}

• When n is large, the binomial variable X is well approximated by a normal with mean np and variance np(1-p), i.e.

$$Z = \frac{X - np}{\sqrt{np(1 - p)}}$$

is approximately standard normal distribution.

• This statement can be converted into a statement about proportions by dividing the numerator and the denominator by n. In particular,

$$Z = \frac{X - np}{\sqrt{np(1 - p)}} = \frac{\hat{p} - p}{\sqrt{p(1 - p)/n}}$$

Sampling distribution of \hat{p}

• The last equation shows that \hat{p} is approximately normally distributed with mean p and variance p(1-p)/n. Let population proportion be p and X is the number having the characteristic in a random sample of size n. Then,

$$\hat{p} = \frac{X}{n}$$

and

$$E(\hat{p}) = p, Var(\hat{p}) = \frac{p(1-p)}{n}, SE(\hat{p}) = \sqrt{\frac{p(1-p)}{n}}$$

Note

Since the population proportion p is unknown, estimated standard error of \hat{p} formulated by,

estimated
$$SE(\hat{p}) = \sqrt{\frac{\hat{p}(1-\hat{p})}{n}}$$

is used during the calculations.

Confidence interval of p

A random sample of size n is selected, and X is the number of success in the sample. Provided that n is large enough,

 $100(1-\alpha)\%$ confidence interval of p:

$$\hat{p} - z_{\alpha/2} \sqrt{\frac{\hat{p}(1-\hat{p})}{n}}$$

where $z_{\alpha/2}$ is the value from the standard normal distribution such that the upper percentile (upper probability) is $\alpha/2$.

Many public polling agencies conduct surveys to determine the current consumer sentiment concerning the state of the economy. For example, the Bureau of Economic and Business Research (BEBR) at the University of Florida conducts quarterly to gauge consumer sentiment in the Sunshine State. Suppose that BEBR randomly samples 484 consumers and finds that only 157 are optimistic about the state of the economy.

Use a 90% confidence interval to estimate the proportion of all consumers in Florida who are optimistic about the state of the economy.

Suppose that BEBR randomly samples 484 consumers and finds that only 157 are optimistic about the state of the economy:

$$\hat{p} = \frac{X}{n} = \frac{157}{484} = 0.324$$

The 90% confidence interval to estimate the proportion of all consumers in Florida who are optimistic about the state of the economy:

$$\hat{p} - z_{\alpha/2} \sqrt{\frac{\hat{p}(1-\hat{p})}{n}}
$$0.324 - z_{0.05} \sqrt{\frac{0.324(1-0.324)}{484}}
$$0.324 - 1.64 \sqrt{\frac{0.324(1-0.324)}{484}}
$$0.289$$$$$$$$

An automobile club which pays for emergency road services (ERS) requested by its members wishes to estimate the proportions of the different types of ERS requests. Upon examining a sample of 2927 ERS calls, it finds that 1499 calls related to starting problems, 849 calls involved serious mechanical failures requiring towing, 498 calls involved flat tires or lockouts, and 81 calls were for other reasons.

- (a) Estimate the true proportion of ERS calls that involved serious mechanical problems requiring towing and determine its 95% margin of error.
- (b) Calculate a 98% confidence interval for the true proportion of ERS calls that related to starting problems.

Examining a sample of 2927 ERS calls, it finds that 1499 calls related to starting problems, <u>849 calls</u> involved serious mechanical failures requiring towing, 498 calls involved flat tires or lockouts, and 81 calls were for other reasons.

(a) Estimate the true proportion of ERS calls that involved serious mechanical problems requiring towing and determine its 95% margin of error = Find CI for 95% confidence level

$$\hat{p} = \frac{X}{n} = \frac{849}{2927} = 0.29$$

$$\hat{p} - z_{\alpha/2} \sqrt{\frac{\hat{p}(1-\hat{p})}{n}}
$$0.29 - 1.96 \sqrt{\frac{0.29(1-0.29)}{2927}}
$$0.2735$$$$$$

Examining a sample of 2927 ERS calls, it finds that 1499 calls related to starting problems, 849 calls involved serious mechanical failures requiring towing, 498 calls involved flat tires or lockouts, and 81 calls were for other reasons.

(b) Calculate a 98% confidence interval for the true proportion of ERS calls that related to starting problems.

$$\hat{p} = \frac{X}{n} = \frac{1499}{2927} = 0.5121$$

$$\hat{p} - z_{\alpha/2} \sqrt{\frac{\hat{p}(1-\hat{p})}{n}}
$$0.5121 - 2.33 \sqrt{\frac{0.5121(1-0.5121)}{2927}}
$$0.4905$$$$$$

^{*} The Z-value for 98% confidence level is obtained from the standard normal distribution table as 2.33.
